

memcpy

memcpy is a function that copies a specified amount of bytes at one address to another address.

```
void *memcpy(void *dest, const void *src, size_t n);
```

It copies the next *n* bytes that *src* points to to the location contained in *dest*. (It also returns **dest**). It does not support regions of memory that overlap.

memcpy must take **pointers** to the bytes to work with to know where they live and where they should be copied to.

```
int x = 5;  
int y = 4;  
memcpy(&x, &y, sizeof(x)); // like x = y
```

memmove

memmove is the same as memcpy, but supports overlapping regions of memory. (Unlike its name implies, it still “copies”).

```
void *memmove(void *dest, const void *src, size_t n);
```

It copies the next n bytes that src points to to the location contained in dest. (It also returns **dest**).

memmove

When might memmove be useful?

Generic Swap

```
void swap(void *data1ptr, void *data2ptr, size_t nbytes) {  
    char temp[nbytes];  
    // store a copy of data1 in temporary storage  
    memcpy(temp, data1ptr, nbytes);  
    // copy data2 to location of data1  
    memcpy(data1ptr, data2ptr, nbytes);  
    // copy data in temporary storage to location of data2  
    memcpy(data2ptr, temp, nbytes);  
}
```

```
char *x = "2";  
char *y = "5";  
swap(&x, &y, sizeof(x));
```

Swap Ends

Let's write a version of swap_ends that works for any type of array.

```
void swap_ends(void *arr, size_t nelems, size_t elem_bytes) {  
    swap(arr, (char *)arr + (nelems - 1) * elem_bytes, elem_bytes);  
}
```

But C still can't do arithmetic with a void*. We need to tell it to not worry about it, and just add bytes. **How can we do this?**

char * pointers already add bytes!
