ASCII

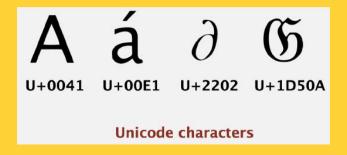

Under the hood, C represents each **char** as an 8-bit *integer* (its "ASCII value").

- Uppercase letters are sequentially numbered
- Lowercase letters are sequentially numbered
- Digits are sequentially numbered
- Lowercase letters are 32 more than their uppercase equivalents (bit flip!)

Unicode Transformation Formats

- The International Standards Organization's (ISO) 16-bit Unicode system can represent every character in every known language, with room for more
- Unicode being somewhat wasteful of space for English documents, ISO also defined several "Unicode Transformation Formats" (UTF), the most popular being UTF-8

ASCII

We can take advantage of C representing each char as an integer:

ASCII

We can take advantage of C representing each **char** as an *integer*:

```
// prints out every lowercase character
for (char ch = 'a'; ch <= 'z'; ch++) {
    printf("%c", ch);
}</pre>
```

Common ctype.h Functions

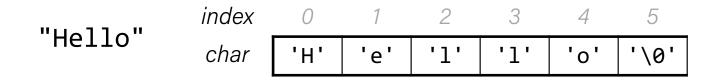

Function	Description
isalpha(<i>ch</i>)	true if <i>ch</i> is 'a' through 'z' or 'A' through 'Z'
islower(<i>ch</i>)	true if <i>ch</i> is 'a' through 'z'
isupper(<i>ch</i>)	true if <i>ch</i> is 'A' through 'Z'
isspace(<i>ch</i>)	true if <i>ch</i> is a space, tab, new line, etc.
isdigit(<i>ch</i>)	true if <i>ch</i> is '0' through '9'
toupper(<i>ch</i>)	returns uppercase equivalent of a letter
tolower(<i>ch</i>)	returns lowercase equivalent of a letter

Remember: these **return** a char; they cannot modify an existing char!

More documentation with man isalpha, man tolower

C Strings

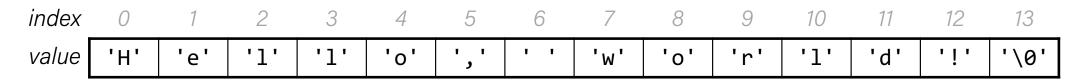

C has no dedicated variable type for strings. Instead, a string is represented as an **array of characters** with a special ending sentinel value.

'\0' is the **null-terminating character**; you always need to allocate one extra space in an array for it.

String Length

Strings are **not** objects. They do not embed additional information (e.g., string length). We must calculate this!

We can use the provided **strlen** function to calculate string length. The null-terminating character does *not* count towards the length.

Caution: strlen is O(N) because it must scan the entire string! We should save the value if we plan to refer to the length later.

Common string.h Functions

Function	Description
strlen(<i>str</i>)	returns the # of chars in a C string (before null-terminating character).
<pre>strcmp(str1, str2), strncmp(str1, str2, n)</pre>	compares two strings; returns 0 if identical, <0 if str1 comes before str2 in alphabet, >0 if str1 comes after str2 in alphabet. strncmp stops comparing after at most n characters.
<pre>strchr(str, ch) strrchr(str, ch)</pre>	character search: returns a pointer to the first occurrence of <i>ch</i> in <i>str</i> , or <i>NULL</i> if <i>ch</i> was not found in <i>str</i> . strrchr find the last occurrence.
strstr(<i>haystack</i> , <i>needle</i>)	string search: returns a pointer to the start of the first occurrence of needle in haystack , or NULL if needle was not found in haystack .
<pre>strcpy(dst, src), strncpy(dst, src, n)</pre>	copies characters in src to dst , including null-terminating character. Assumes enough space in dst . Strings must not overlap. strncpy stops after at most n chars, and <u>does not</u> add null-terminating char.
<pre>strcat(dst, src), strncat(dst, src, n)</pre>	concatenate src onto the end of dst . strncat stops concatenating after at most n characters. Always adds a null-terminating character.
strspn(<i>str, accept</i>), strcspn(<i>str, reject</i>)	strspn returns the length of the initial part of str which contains only characters in accept. strcspn returns the length of the initial part of str which does not contain any characters in reject.

The string library: strcmp

strcmp(str1, str2): compares two strings.

- returns 0 if identical
- <0 if **str1** comes before **str2** in alphabet
- >0 if **str1** comes after **str2** in alphabet.

```
int compResult = strcmp(str1, str2);
if (compResult == 0) {
      // equal
} else if (compResult < 0) {
      // str1 comes before str2
} else {
      // str1 comes after str2
}</pre>
```

Copying Strings – strcpy

We must make sure there is enough space in the destination to hold the entire copy, *including the null-terminating character*.

Writing past memory bounds is called a "buffer overflow". It can allow for security vulnerabilities!

char * vs. char[]

```
char myString[]
     vs
char *myString
```

You can create **char** * pointers to point to any character in an existing string and reassign them since they are just pointer variables. You **cannot** reassign an array.
